Driven by computer technology, communication technology and intellectual technology, Industrial Control Systems (ICSs) develop towards the direction of intellectualization and network.

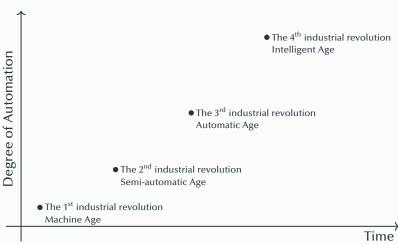

Driven by computer technology, communication technology and intellectual technology, Industrial Control Systems (ICSs) develop towards the direction of intellectualization and network.

- ICSs have been widely applied in various industry of the national economy and people's livelihood, and gradually become
 the brain and central nervous of critical infrastructure and all
 kinds of industrial production.
- Once abnormal situation appears in ICSs, serious accidents may be happen, which may cause damage to property, people or a wide range of environment.

- In 2010, Stuxnet attacked Iran's nuclear power plants and ruined almost one-fifth of Iran's nuclear centrifuges.
- In 2013, Israel Haifa highway control system was attacked by hackers, which caused massive traffic congestion in the city which lead great loss and serious subsequent problems.
- In 2014, Havex malware infects many industrial control system in European and caused the leakage of large amounts of data.

Problems – Timeliness and Availability

ICSs have rigorous requirements on timeliness and availability. The cybersecurity risks of ICSs are primarily from the potential loss caused by the cyber-attacks which demolish the timeliness and availability of the control system.

In order to achieve the destructive purpose, attackers generally need to follow part or all of these three steps:

- 1. infiltrate into the field network,
- 2. invalidate the system functions,
- 3. cause the hazardous incidents.

Therefore, the cybersecurity risk assessment of ICSs needs a novel and targeted risk model to analyze the risk propagation.

Problems – Overlapping amongst Consequences

The majority of existing quantitative risk assessment approaches used the following definition to calculate the risk \mathcal{R} .

$$\mathcal{R} = \sum_{i} S(e_i) P(e_i)$$

However, the overlapping amongst difference consequences may cause the error of risk value. For example,

incident e_1 is the temperature anomaly of reactor, incident e_2 is the explosion of reactor, when e_1 or e_2 happens, the product will be damaged.

Assume that $P(e_1) = 1$, so $P(e_2) = p_1$, then

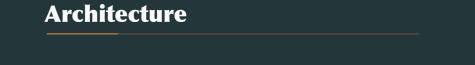

$$\mathscr{R} = S(e_1) + p_1 S(e_2) = S(e_1) + p_1 S(e_1) = (1 + p_1) S(e_1) \ge S(e_1).$$

Problems – Unknown Attacks

Many ICSs run 24/7/365, and therefore the updates must be planned and scheduled days or weeks in advance. After the updates, exhaustive testing is necessary to ensure the high availability of the ICS.

This leads to inability of the attack knowledge of ICSs to be updated in time. Several attack knowledge-based risk assessments cannot work well on ICSs.

Therefore, the risk assessment should have the ability of assessing the risk caused by unknown attacks without the corresponding attack knowledge.

12

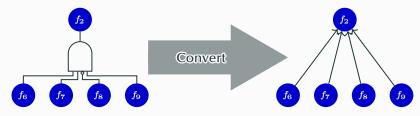

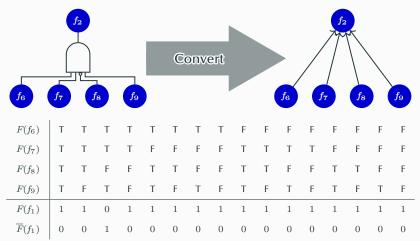

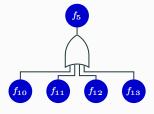

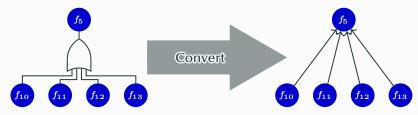

To simplify the inference, the function tree is converted into Bayesian network, which is shown in following figure.

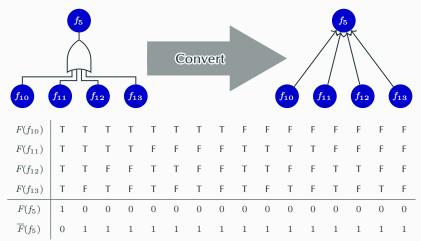

13

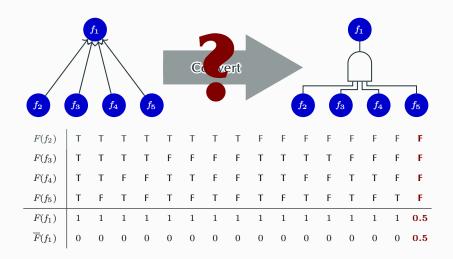

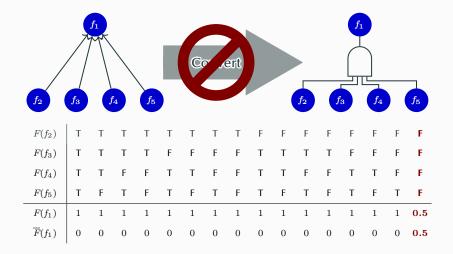

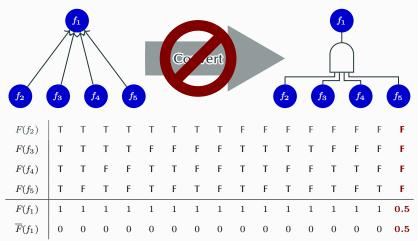

The conditional probability table of the Bayesian network contains more information than the logical gate of the fault tree.

The occurrence of one incident may cause another incidents, in this paper, the Bayesian network is also used to model the causal relationship amongst the potential incidents.

Information Transfer between Levels

The cyber attacks can lead to system function failures, and the function failures may cause the industrial incidents. To analyze the risk propagation, an information transfer is necessary between the three aforementioned layers.

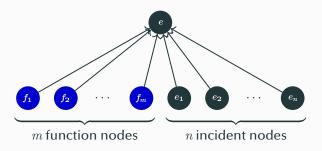

The following figures show two kind of information transfer.

Information Transfer between Levels

The cyber attacks can lead to system function failures, and the function failures may cause the industrial incidents. To analyze the risk propagation, an information transfer is necessary between the three aforementioned layers.

The following figures show two kind of information transfer.

Collection of Evidence

There are two kind of evidence need to be collected:

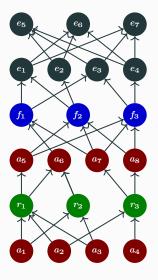

- **Attack Evidence**, contains the attack information, such as attack time, attack type, attack object, etc.
- Anomaly Evidence, contains the information about the anomaly, such as function failure, function restoration, incident occurrence, etc.

Collection of Evidence

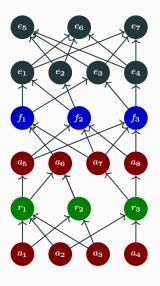

There are two kind of evidence need to be collected:

- **Attack Evidence**, contains the attack information, such as attack time, attack type, attack object, etc.
- Anomaly Evidence, contains the information about the anomaly, such as function failure, function restoration, incident occurrence, etc.

For each evidence, there exists a corresponding node in the multilevel Bayesian network. When the intrusion detection system or the monitoring system finds an evidence, the corresponding node will be marked in the multi-level Bayesian network.

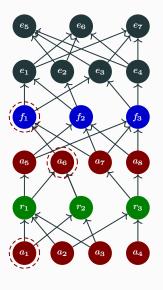

The left figure shows a typical multi-level Bayesian network.

$$a_1, a_6, f_1$$

Then the nodes a_1 , a_6 , and f_1 are marked with **red** dashed circles.

Finally, the algorithm named Probability Propagation in Trees of Clusters (PPTC) can calculate the probabilities of all the hazardous incidents.

Dynamic Risk Assessment

for each incident e_i , analyze its consequence and generate a consequence set

$$\boldsymbol{c}_i = (c_1, c_2, \cdots, c_n).$$

The meaning of c_i is that the occurring of the incident e_i will threaten the elements in consequence set c_i .

For example, the incident e_i is an explosion of a reactor, which may cause worker casualties, air pollution, facilities damages, and products loss. The consequence set of e_i is

 $c_i = (workers, air, facilities, products).$

For each $c'_j \in C'$, generate a corresponding auxiliary node x_j . According to the **traceability** of C'

$$\forall c' \in C', \exists c \in C, c' \subseteq c,$$

there must be a consequence set $c_i \in C$, where $c_j' \subseteq c_i$.

For each $c'_j \in C'$, generate a corresponding auxiliary node x_j . According to the **traceability** of C'

$$\forall c' \in C', \exists c \in C, c' \subseteq c,$$

there must be a consequence set $c_i \in C$, where $c_j' \subseteq c_i$. So, for each $c_j' \in C'$, we can find the incident set

$$\boldsymbol{e}_j=(e_{i_1},e_{i_2},\cdots,e_{i_n}).$$

For each $c'_j \in C'$, generate a corresponding auxiliary node x_j . According to the **traceability** of C'

$$\forall c' \in C', \exists c \in C, c' \subseteq c,$$

there must be a consequence set $c_i \in C$, where $c_j' \subseteq c_i$. So, for each $c_j' \in C'$, we can find the incident set

$$e_j = (e_{i_1}, e_{i_2}, \cdots, e_{i_n}).$$

For each incident e_k of the incident set e_j , the corresponding consequence set c_k satisfies the following condition:

$$c'_j \subseteq c_k$$
.

For each $c'_j \in C'$, generate a corresponding auxiliary node x_j . According to the **traceability** of C'

$$\forall c' \in C', \exists c \in C, c' \subseteq c,$$

there must be a consequence set $c_i \in C$, where $c_j' \subseteq c_i$. So, for each $c_i' \in C'$, we can find the incident set

$$\boldsymbol{e}_j=(e_{i_1},e_{i_2},\cdots,e_{i_n}).$$

For each incident e_k of the incident set e_j , the corresponding consequence set c_k satisfies the following condition:

$$c'_j \subseteq c_k$$
.

Therefore, the parent nodes of the auxiliary node x_j are incident nodes $e_{i_1}, e_{i_2}, \dots, e_{i_m}$.

For each auxiliary node x_j , generate a conditional probability table. A typical conditional probability table of auxiliary node x_j is shown as following table.

$H(e_{i_1})$	Т	T	Т		F	F	F
$H(e_{i_2})$	Т	T	T		F	F	F
$H(e_{i_3})$	Т	T	T		F	F	F
÷	:	:	:	٠٠.	:	:	:
$H(e_{i_{n-2}})$	Т	T	T		F	F	F
$H(e_{i_{n-1}})$	Т	T	F		T	F	F
$H(e_{i_n})$	Т	F	F		F	Т	F
$H(x_j)$	1	1	1		1	1	0
$\overline{H}(x_j)$	0	0	0		0	0	1

Classification of Incident Consequences

In this paper, there are three main kinds of incident consequences to be considered:

· Harm to Humans:

- temporary harm,
- permanent disability,
- fatality.

· Environmental Pollution:

- air pollution,
- soil contamination,
- water pollution.

· Property Loss:

- damage of materials,
- damage of products,
- damage of equipment.

Quantification of Incident Consequences

· Harm to Humans Q_H :

If the decision-maker would like to increase the cost of an investment by Δc to reduce the probability of a fatality by Δp ,

$$Q_H = \Delta c / \Delta p$$
.

· Environmental Pollution Q_E :

The monetary loss of environmental pollution is defined as

$$Q_E = Penalty + Compensation + Harness Cost.$$

• Property Loss Q_P :

The cost of replacement is used to quantify the loss of property Q_P , such as the loss of materials, products, and equipment.

Calculation of Dynamic Risk

Due to the following two reasons:

- there is no overlapping between the consequences of any two auxiliary nodes x_i and x_j , $i \neq j$,
- · the auxiliary nodes contain all the consequences of incidents,

the dynamic cybersecurity risk can be defined as

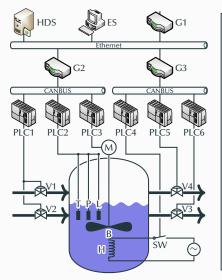

$$\mathscr{R} = \sum_{i=1}^{m'} p(x_i) q(x_i),$$

where

- $p(x_i)$ is the occurrence probability of the auxiliary node x_i ,
- · $q(x_i)$ is the monetary loss of the auxiliary node x_i .

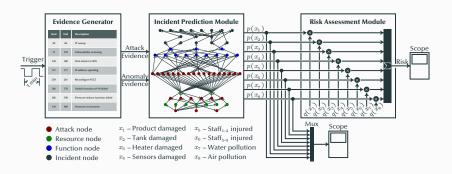

The simulation object is a chemical reactor whose control structure is shown as the following figure.

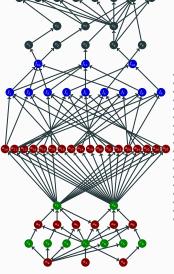

_ Legend				
HDS	Historical data server			
ES	Engineer station			
G1	Gateway of Ethernet			
G2	Gateway of CANBUS			
G3	Gateway of CANBUS			
PLC1	Controller of V1 and V2			
PLC2	Data collection of P, T and L			
PLC3	Controller of M

286	390	Pressure reduce function failed	$F(f_{12})$
310	400	Pressure is excessive	$H(e_4)$

The quantification of consequences is shown as following table.

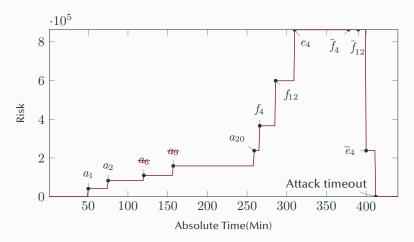

Incident Symbol	Description of Incident	Quantification of Consequence(\$)
x_1	Product damaged	50,000
x_2	Tank damaged	500,000
x_3	Heater damaged	10,000
x_4	Sensors damaged	10,000
x_5	Staff ₁₋₄ injured	800,000
x_6	Staff ₅₋₉ injured	1,000,000
x_7	Water pollution	200,000
x_8	Air pollution	200,000

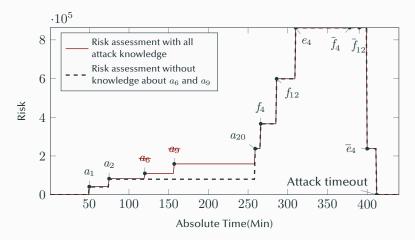

In the previous simulation, the curve of the cybersecurity risk is shown as the **red** line in the following figure.

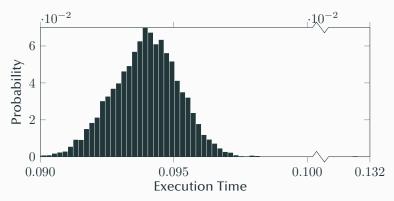

To validate the ability to deal with the unknown attacks, the attack knowledge about attack and attack is removed from the multilevel Bayesian network.

Then an identical multi-step attack on the system is launched to the system. The new cybersecurity risk curve is shown the dashed line in the following figure.

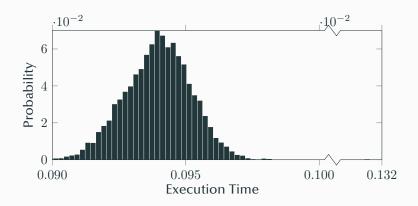

We repeat the first simulation 5,000 times, and the execution time of 5,000 calculations is recorded. This simulation is run on a machine with Intel Pentium processor G3220 (3M Cache, 3.00GHz) and 4GB DDR3 memory. The following figure shows the distribution of the 5,000 execution times.

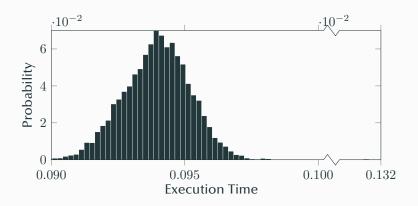

Some parameters of the following figure:

 \cdot The average execution time of a risk assessment is 94.1ms.

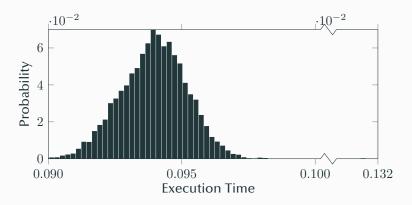

Some parameters of the following figure:

- The average execution time of a risk assessment is 94.1ms.
- The minimum execution time of a risk assessment is 89.9ms.

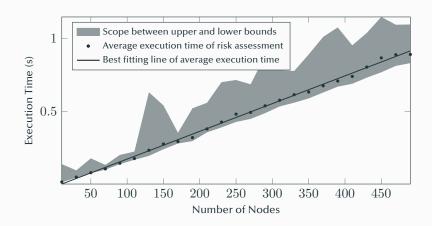

Some parameters of the following figure:

- The average execution time of a risk assessment is 94.1ms.
- The minimum execution time of a risk assessment is 89.9ms.
- The maximum execution time of a risk assessment is 131.6ms.

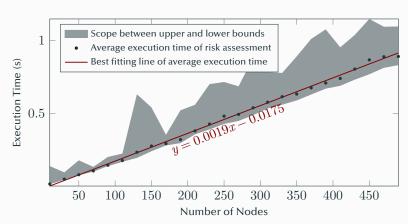

Finally, 25 multi-level Bayesian networks with different node sizes are adopted to show the possible upper/lower bounds and the scalability of our approach.

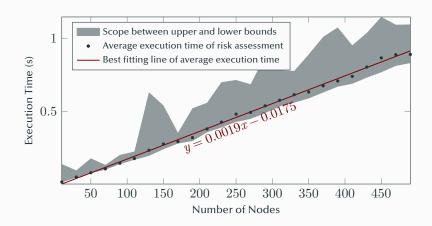

In the following figure, the fitting line

$$y = 0.0019x - 0.0175$$

matches well with the correlation coefficient r = 0.9987.

This means that the execution time of the risk assessment scales linearly with the increase of the node size of the multi-level Bayesian network.

Conclusion and Prospect

 By considering the characteristics of ICSs, a novel multi-level Bayesian network was proposed, which integrated a knowledge of attack, system function, and hazardous incident.

- By considering the characteristics of ICSs, a novel multi-level Bayesian network was proposed, which integrated a knowledge of attack, system function, and hazardous incident.
- The attack knowledge and system knowledge were combined to analyze the potential impact of attacks, so the proposed approach had the ability of assessing the risk caused by unknown attacks.
